Python Data Structures Cheat Sheet

List

Package/Method	Description	Code Example
		Syntax: list_name.append(element)
append()	The 'append()' method is used to add an element to the end of a list.	<pre>Example: fruits = ["apple", "banana", "orange"] fruits.append("mango") print(fruits)</pre>
copy()	The 'copy()' method is used to create a shallow copy of a list.	Example 1: my_list = [1, 2, 3, 4, 5] new_list = my_list.copy() print(new_list) # Output: [1, 2, 3, 4, 5]
count()	The 'count()' method is used to count the number of occurrences of a specific element in a list in Python.	Example: my_list = [1, 2, 2, 3, 4, 2, 5, 2] count = my_list.count(2) print(count) # Output: 4
Creating a list	A list is a built-in data type that represents an ordered and mutable collection of elements. Lists are enclosed in square brackets [] and elements are separated by commas.	<pre>Example: fruits = ["apple", "banana", "orange", "mango"]</pre>
del	The 'del' statement is used to remove an element from list. 'del' statement removes the element at the specified index.	Example: my_list = [10, 20, 30, 40, 50] del my_list[2] # Removes the element at index 2 print(my_list) # Output: [10, 20, 40, 50]

about:blank 1/6

+/10/2023, 10.10	1	about.blailk
extend()	The 'extend()' method is used to add multiple elements to a list. It takes an iterable (such as another list, tuple, or string) and appends each element of the iterable to the original list.	<pre>Example: fruits = ["apple", "banana", "orange"] more_fruits = ["mango", "grape"] fruits.extend(more_fruits) print(fruits)</pre>
		<pre>Example: my_list = [10, 20, 30, 40, 50] print(my_list[0]) # Output: 10 (accessing the first element) print(my_list[-1]) # Output: 50 (accessing the last element using negative indexing)</pre>
Indexing	Indexing in a list allows you to access individual elements by their position. In Python, indexing starts from 0 for the first element and goes up to `length_of_list - 1`.	Syntax:
insert()	The `insert()` method is used to insert an element.	list_name.insert(index, element) Example:
	eternetic.	<pre>my_list = [1, 2, 3, 4, 5] my_list.insert(2, 6) print(my_list)</pre>
Modifying a list	You can use indexing to modify or assign new values to specific elements in the list.	Example: my_list = [10, 20, 30, 40, 50] my_list[1] = 25 # Modifying the second element print(my_list) # Output: [10, 25, 30, 40, 50]

about:blank 2/6

```
Example 1:
                                                                                                            my\_list = [10, 20, 30, 40, 50] removed_element = my\_list.pop(2) # Removes and returns the element at index 2
                                                                                                            print(removed_element)
# Output: 30
                                                                                                            print(my_list)
# Output: [10, 20, 40, 50]
                              'pop()' method is another way to remove an
                             element from a list in Python. It removes and
                             returns the element at the specified index. If
pop()
                             you don't provide an index to the 'pop()'
                                                                                                    Example 2:
                             method, it will remove and return the last
                             element of the list by default
                                                                                                            \label{eq:my_list} \begin{split} &\text{my\_list} = [\text{10, 20, 30, 40, 50}] \\ &\text{removed\_element} = &\text{my\_list.pop()} \text{ \# Removes and returns the last element} \end{split}
                                                                                                            print(removed_element)
# Output: 50
                                                                                                            print(my_list)
# Output: [10, 20, 30, 40]
                                                                                                    Example:
                                                                                                            my_list = [10, 20, 30, 40, 50]
my_list.remove(30) # Removes the element 30
print(my_list)
# Output: [10, 20, 40, 50]
                             To remove an element from a list. The
remove()
                              `remove()` method removes the first
                              occurrence of the specified value.
                                                                                                    Example 1:
                                                                                                            my_list = [1, 2, 3, 4, 5]
my_list.reverse() print(my_list)
                                                                                                             # Output: [5, 4, 3, 2, 1]
                              The 'reverse()' method is used to reverse the
reverse()
                             order of elements in a list
                              You can use slicing to access a range of
Slicing
                                                                                                    Syntax:
                             elements from a list.
                                                                                                            list_name[start:end:step]
                                                                                                    Example:
                                                                                                            my_list = [1, 2, 3, 4, 5]
print(my_list[1:4])
# Output: [2, 3, 4] (elements from index 1 to 3)
print(my_list[:3])
# Output: [1, 2, 3] (elements from the beginning up to index 2)
print(my_list[2:])
# Output: [3, 4, 5] (elements from index 2 to the end)
print(my_list[::2])
```

about:blank 3/6

J4/10/2025, 18:18			about:blank
			# Output: [1, 3, 5] (every second element)
	sort()	The 'sort()' method is used to sort the elements of a list in ascending order. If you want to sort the list in descending order, you can pass the 'reverse=True' argument to the 'sort()' method.	Example 1: my_list = [5, 2, 8, 1, 9] my_list.sort() print(my_list) # Output: [1, 2, 5, 8, 9] Example 2: my_list = [5, 2, 8, 1, 9] my_list.sort(reverse=True) print(my_list) # Output: [9, 8, 5, 2, 1]

Tunle

Package/Method	Description	Code Example
count()	The count() method for a tuple is used to count how many times a specified element appears in the tuple.	<pre>Syntax: tuple.count(value) Example: fruits = ("apple", "banana", "apple", "orange") print(fruits.count("apple")) #Counts the number of times apple is found in tuple #Output: 2</pre>
index()	The index() method in a tuple is used to find the first occurrence of a specified value and returns its position (index). If the value is not found, it raises a ValueError.	Syntax: tuple.index(value)
		Example:

about:blank 4/6

04/1	4/10/2025, 18:18 about:blank		
			print(fruits.index("apple")) #Returns the index value at which apple is present. #Output: 0
s	um()	The sum() function in Python can be used to calculate the sum of all elements in a tuple, provided that the elements are numeric (integers or floats).	<pre>Syntax: sum(tuple) Example: numbers = (10, 20, 5, 30) print(sum(numbers)) #Output: 65</pre>
n	nin() and max()	Find the smallest (min()) or largest (max()) element in a tuple.	Example: numbers = (10, 20, 5, 30) print(min(numbers)) #Output: 5 print(max(numbers)) #Output: 30
lo	en()	Get the number of elements in the tuple using len().	<pre>Syntax: len(tuple) Example: fruits = ("apple", "banana", "orange") print(len(fruits)) #Returns length of the tuple. #Output: 3</pre>
